ON THE GEOMETRY OF WIMAN’S SEXTIC

NAOKI INOUE AND FUMIHARU KATO

Abstract. We give a new version of W.L. Edge’s construction of the linear system of plane sextics containing Wiman’s sextic, by means of configuration space of 5 points on projective line. This construction reveals out more of the inner beauty of the hidden geometry of Wiman’s sextic. Furthermore, it allows one to give a friendly proof for the fact that the linear system is actually a pencil, the fact that is important in both Edge’s and our constructions.

1. Introduction

Consider the action of the symmetric group $S_5$ of five letters on the projective 5-space $\mathbb{P}^5$ defined over an algebraically closed field $K$ of characteristic not equal to 2, 3, 5, induced from the 6-dimensional irreducible representation. Calculating the symmetric square of the representation, one sees that there exists a quadratic form in $H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(2))$, unique up to scalar, that is invariant by any element of $S_5$. This gives rise to the unique quadratic hypersurface in $\mathbb{P}^5$, which is stable under the action of $S_5$.

There is, on the other hand, the famous surface embedded in $\mathbb{P}^5$, the Del Pezzo quintic surface, on which the group $S_5$ acts equivariantly with the action on $\mathbb{P}^5$ as above. The intersection of the hypersurface with the Del Pezzo quintic surface defines a curve, denoted by $\tilde{W}$. By the 4-point blow-up map, it is mapped to a certain curve on $\mathbb{P}^2$, which is stable under the $S_5$-action by Cremona transformations. This curve is actually an irreducible 4-nodal sextic, which we denote by $W$. The actual equation for $W$ with respect to a suitably chosen homogeneous coordinate is given as follows:

$$x^6 + y^6 + z^6 + (x^2 + y^2 + z^2)(x^4 + y^4 + z^4) - 12x^2y^2z^2 = 0.$$  

The curve $W$ is first discovered by Wiman in the end of 19th century [5]. This curve is, needless to say, interesting in its own light, for it has a lot of symmetries; the normalization of $W$ is actually isomorphic to $\tilde{W}$ as above, which is, therefore, a non-singular projective curve of genus 6 having the automorphism group isomorphic to $S_5$. But more attractive is the inner beauty of the rich geometry hidden behind the curve $W$. In his 1981 papers [2][3] W.L. Edge, unsatisfied with Wiman’s original description of the curve, gave projective geometric characterization of the Wiman’s sextic, which reveals out rich geometric background and several nice properties. In the first work Edge constructed in a purely projective geometric manner a pencil $L$ of plane sextics on which the group $S_5$ acts by Cremona transformations. As the non-trivial action of $S_5$ on projective line is only possible by the signature action, there are precisely two members in $L$ that are stable under the action. One of them is a union of 6 lines, and the other is the Wiman’s sextic. Notice that, in order to find the Wiman’s sextic in $L$, it was important to know that his linear system $L$ is actually a pencil.

In this note we are going to recast Edge’s construction in a slightly different manner. The main points of our method are that we regard the Del Pezzo quintic surface as the...
configuration space of 5 points on $\mathbb{P}^2$, and that we consider the so-called \textit{pentagonal coordinates} (studied by M. Yoshida [1]) on the surface, which has 6 variables $X, Y, Z, U, V, W$ together with 6 dummy ones $X^*, Y^*, Z^*, U^*, V^*, W^*$, and gives the anti-canonical embedding into $\mathbb{P}^5$. There are several benefits arising from these points. First, by means of the configuration space of 5 points, the natural $S_3$-action becomes visible; moreover, the action can be quite explicitly described in terms of the pentagonal coordinates. This allows one to understand the construction more transparently. Secondly, our method allows to give a friendly proof of the fact that the linear system $L$ is a pencil, the fact for which Edge only gives a short explanation. Finally, as the reader will find soon, the pentagonal coordinates turns out to be the most optimal coordinate system in the sense that, in terms of it, the Wiman’s sextic has the very beautiful and simple defining equation; indeed, it is

$$X^2 + X^* + Y^2 + Y^* + Z^2 + Z^* + U^2 + U^* + V^2 + V^* + W^2 + W^* = 0$$

(cf. 3.19 below). Note that our coordinate system is different from Edge’s one in [3].

The composition of this note is as follows: In the next section, we will briefly recall Edge’s construction of the linear system $L$ and the Wiman’s sextic $W$. In Section 3 we will perform our way of the construction. In the last section (Section 4) we give the proof of the fact that the linear system is a pencil.

2. Review of Edge’s construction

In this section we will briefly review Edge’s construction of Wiman’s sextic [2].

\textbf{General Convention.}

2.1. Throughout this paper, $K$ denotes an algebraically closed field with $\text{char}(K) \neq 2, 3, 5$. By $V = K^{n+1}$ we denote the vector space consisting of all column vectors $(a_0, \ldots, a_n)$ of height $n + 1$. Set $\mathbb{P}^n = \text{Proj} \text{Sym}_K V^*$. The set of $K$-rational points $\mathbb{P}^n(K)$ thus consists of homothecy classes of column vectors; such a point will be written as $(a_0 : \cdots : a_n)$, or more simply, $(a_0 : \cdots : a_n)$, if there is no danger of confusion. The group $\text{PGL}_{n+1}(K)$ naturally acts on $\mathbb{P}^n$ from the left. On $K$-rational points, the action is described as follows: For $A = (a_{ij})$ and $x = (x_0 : \cdots : x_n)$, we have $Ax = (y_0 : \cdots : y_n)$, where $(y_0, \cdots, y_n) = A \cdot (x_0, \cdots, x_n)$.

2.2. In the sequel, simply by a point of a $K$-scheme we always mean a $K$-rational point. Accordingly, for a $K$-scheme $X$, writing $x \in X$ means that $x$ is a $K$-rational point of $X$, that is, $x \in X(K)$.

2.3. We will be concerned with some elementary projective plane geometry. For two distinct points $p_0, p_1 \in \mathbb{P}^2$, we denote by $p_0 * p_1$, the so-called \textit{join}, the line spanned by these points. For two different lines $\ell_0, \ell_1$ on $\mathbb{P}^2$, we likewise denote by $\ell_0 * \ell_1$ the join, that is, the unique intersection point of them.

\textbf{Cremona transformation.}

2.4. Recall that a \textit{Cremona transformation} on $\mathbb{P}^n$ is a rational selfmap of $\mathbb{P}^n$ that has the rational inverse. They evidently form a group by composition, which contains $\text{Aut}(\mathbb{P}^n) = \text{PGL}_{n+1}(K)$ as a subgroup. The Cremona transformations of the following kind will be of particular importance: Let $p_0, p_1, p_2, q \in \mathbb{P}^2$ be four points in general position (i.e., no three of them sit on a line), and $Q$ the blow-up of $\mathbb{P}^2$ at the three points $p_0, p_1, p_2$. Let $E_i$ ($i = 0, 1, 2$) be the resulting exceptional line over $p_i$, and $C_i$ the strict transform of the line $p_j * p_k$, where $\{i, j, k\} = \{0, 1, 2\}$. Blow-down the $(-1)$-curves $C_0, C_1, C_2$, and coordinate the resulting $\mathbb{P}^2$ in such a way that the image of $C_i$ is $p_i$ and that $q$ is mapped to $q$. Thus
we get a Cremona transformation, which we denote by $J_{\{p_0,p_1,p_2\},q}$. Note that $J_{\{p_0,p_1,p_2\},q}$ is involutive, i.e., $(J_{\{p_0,p_1,p_2\},q})^2 = \text{id}$. The following proposition is easy to verify, and the proof is left to the reader:

**Proposition 2.5.** The Cremona transformation $J_{\{p_0,p_1,p_2\},q}$ maps the pencil of all lines passing through $p_i$ linearly isomorphically onto itself for each $i = 0, 1, 2$, and maps the pencil of all lines passing through $q$ linearly isomorphically onto the pencil of all conics passing through $p_0, p_1, p_2, q$ and vice versa.

**Hessian duad and Hessian pair.**

2.6. Consider a set of three distinct points $\{p_0, p_1, p_2\}$ of $\mathbb{P}^1$. The **Hessian duad** of the set $\{p_0, p_1, p_2\}$ is the set of two points $\{q^+, q^-\}$ of $\mathbb{P}^1$ characterized by one of the following equivalent conditions:

1. The points $q^+$ and $q^-$ are the fixed points of the linear transformation of $\mathbb{P}^1$ induced from a cyclic permutation of $\{p_0, p_1, p_2\}$.
2. $q = q^+$ and $q = q^-$ are the solutions for the equation $\text{cr}(p_0, p_1, p_2, q) = -\omega, -\omega^2$, where $\omega$ is the primitive cubic root of unity.
3. If we choose $\varphi \in \text{Aut}(\mathbb{P}^1)$ such that $\varphi(\{p_0, p_1, p_2\}) = \{1, \omega, \omega^2\}$, then $\varphi(\{q^+, q^-\}) = \{0, \infty\}$.

Here, $\text{cr}(p_0, p_1, p_2, q)$ denotes the **cross ratio** defined by

$$\text{cr}(p_0, p_1, p_2, q) = \frac{q - p_1}{q - p_2} \cdot \frac{p_0 - p_2}{p_0 - p_1},$$

where, now, the points are displayed in terms of inhomogeneous coordinate.

Note that the definition of Hessian duad depends only on the set $\{p_0, p_1, p_2\}$. One can similarly define Hessian duad of three distinct points on a line in $\mathbb{P}^2$. In duality, one defines likewise the notion of Hessian pair of the set of three distinct lines sitting in a pencil. The following proposition is easy to see, and the proof is left to the reader:

**Proposition 2.7.** Let $p$ be a point of $\mathbb{P}^2$, and $\{\ell_0, \ell_1, \ell_2\}$ a set of distinct three lines passing through $p$. Let $\ell$ be a line that does not contain $p$, and set $q_i = \ell_i * \ell$ for $i = 0, 1, 2$. Then the following conditions for two lines $\ell^\pm$ passing through $p$ are equivalent:

1. $\{\ell^+, \ell^-\}$ is the Hessian pair of $\{\ell_0, \ell_1, \ell_2\}$.
2. $\{\ell^+ * \ell, \ell^- * \ell\}$ is the Hessian duad of $\{q_0, q_1, q_2\}$ on the line $\ell$.

**The line configuration $(\Pi + H)$.**

2.8. Now we begin the construction. The first step of the construction is to give a certain line configuration, which we denote symbolically by $(\Pi + H)$, on $\mathbb{P}^2$ that is determined by a set of 4 points in general position; since the construction is entirely linear, change of the set of the points only gives rise to the linear change of the configuration, and hence, $(\Pi + H)$ is unique up to linear transformation.

Let $\{p_1, p_2, p_3, p_4\}$ be a set of 4 points of $\mathbb{P}^2$ in general position. This set gives rise to the so-called **quadrangle** on $\mathbb{P}^2$, which is the line configuration consisting of 6 lines $L_{ij} = L_{ji} = p_k * p_l$ for $\{i, j, k, l\} = \{1, 2, 3, 4\}$. It has the points $p_i$’s as its vertices, and the 3 diagonal points $p_{ij} = p_{kl} = L_{ij} * L_{kl}$ for $\{i, j, k, l\} = \{1, 2, 3, 4\}$. Note that, on the line $L_{ij}$, there are 3 distinguished points $p_k, p_l, p_{kl}$ $\{i, j, k, l\} = \{1, 2, 3, 4\}$, where the first two are triple points, and the last one is a double point. We denote by $\Pi$ the line configuration consisting of the 6 lines $L_{ij}$.
2.9. Let \( \{i,j,k,l\} = \{1,2,3,4\} \). The 3 lines \( L_{kl}, L_{jl}, L_{ij} \) pass through the vertex \( p_i \), and one can consider the Hessian pair \( \{H_i^+, H_i^-\} \) of them. We have in total 8 lines of the form \( H_i^\pm \), which we call the Hessian lines of the quadrangle. The line configuration consisting of the 8 lines \( H_i^\pm \) is denoted by \( H \).

On the line \( L_{ij} \), one can consider the Hessian dual \( \{q_{ij}^+, q_{ij}^-\} \) of \( \{p_k, p_l, p_{kl}\} \). By 2.7, it coincides with the pair \( \{H_i^+ * L_{ij}, H_i^- * L_{ij}\} \), and furthermore, with the pair \( \{H_j^+ * L_{ij}, H_j^- * L_{ij}\} \). In this way, we get 12 points of the form \( q_{ij}^\pm \). We call them the Hessian points of the quadrangle \( \Pi \).

**Definition 2.10.** The line configuration \( \Pi + H \) is the collection of 6 lines \( L_{ij} \) (edges of the quadrangle) and the 8 lines \( H_i^\pm \) (hessian lines), hence in total 14 lines. It has in total the 19 distinguished points, viz., 4 vertices \( p_i \), 3 diagonal points \( p_{ij} \), and 12 Hessian points \( q_{ij}^\pm \).

**Cremona action by \( S_5 \) on \( \mathbb{P}^2 \).**

2.11. Let \( H \) be the group of the linear transformations induced by permutations of four points \( p_1, p_2, p_3, p_4 \). Thus, \( H \) is a subgroup of \( \text{Aut}(\mathbb{P}^2) \) isomorphic to \( S_4 \). Moreover, it is obvious that the line configuration \( \Pi + H \) is stable under the action by \( H \).

To understand the symmetry more in detail, let us introduce the following 5 pencils:

- \( \alpha_0 \): the pencil of conics passing through \( p_1, p_2, p_3, p_4 \).
- \( \alpha_i \) \((i = 1, 2, 3, 4)\): the pencil of lines passing through \( p_i \).

The group \( H \) acts on the set \( \{\alpha_0, \alpha_1, \alpha_2, \alpha_3, \alpha_4\} \) as the permutations of the last four elements.

Set \( J_i = J_{\{p_i, p_{jkl}\}} \) for \( \{i,j,k,l\} = \{1,2,3,4\} \). By 2.5, we readily see the following:

**Proposition 2.12.** The Cremona transformation \( J_i \) gives rise to the transposition \( (\alpha_0\alpha_i) \) on the set \( \{\alpha_0, \alpha_1, \alpha_2, \alpha_3, \alpha_4\} \).

2.13. Now set \( G = \langle H, J_1 \rangle \) as a subgroup of the group of all Cremona transformations. Since \( G \) acts on the set \( \{\alpha_0, \alpha_1, \alpha_2, \alpha_3, \alpha_4\} \), there exists a map \( G \to S_5 \). As the image contains all transpositions, this map is surjective; one can check, moreover, without so much pain that it is injective, and thus that the group \( G \) is isomorphic to \( S_5 \). Hence we get the Cremona action of \( S_5 \) on \( \mathbb{P}^2 \). Note that the group \( G \) contains all \( J_i \) \((i = 1, 2, 3, 4)\) as conjugates of \( J_1 \) by suitable elements in \( H \). By the construction of \( J_i \)’s (as in 2.4), we see the following:

**Proposition 2.14.** The line configuration \( \Pi + H \) is stable under the action of \( G \).

The line system \( L \).

**Definition 2.15.** Define \( L \) to be the linear system of curves on \( \mathbb{P}^2 \) spanned by general 4-nodal sextics \( C \) having the nodes at the vertices \( p_1, p_2, p_3, p_4 \) such that the following conditions are satisfied:

1. For each \( i = 1, 2, 3, 4 \), the nodal tangents at \( p_i \) coincide with \( H_i^\pm \).
2. For each \( i, j = 1, 2, 3, 4 \( i \neq j \), \( C \) passes through the points \( q_{ij}^\pm \).

Note that, due to 2.14, the line system \( L \) is acted on by the group \( G \cong S_5 \).

**Wiman’s sextic \( W \).**

2.16. Edge claims in [2], with a short explanation, that the linear system \( L \) is a pencil. We will give an algebro-geometric proof for this fact in Section 4. Assuming this fact, as well
as that the action of $G$ on $L$ is not the trivial one, one can characterize the Wiman’s sextic curve $W$ as the unique irreducible member of $L$ that is stable under the action of the whole group $G$. In fact, since the action of $G$ on $L$ is non-trivial, $G$ acts on $L \cong \mathbb{P}^1$ via the map

$$G \cong \mathfrak{S}_5 \longrightarrow \mathfrak{S}_5/\mathfrak{A}_5 \cong \{ \pm 1 \},$$

namely:

1. general member of $L$ is stable under the action of $\mathfrak{A}_5$;
2. there exist exactly 2 members (corresponding to the fixed point in $\mathbb{P}^1$ of the action $z \mapsto -z$) which are stable under the whole group $G = \mathfrak{S}_5$.

As we will see in the next section that, in fact, one of the members as in (2) is $\Pi$, and the other one is an irreducible one, which is nothing but Wiman’s sextic.

3. Construction by configuration space

**Configuration space.**

3.1. We denote by $X(2,n)$ the $K$-scheme representing the set of all configurations of $n$ rational points on the projective line $\mathbb{P}^1$, that is,

$$X(2,n) = \text{PGL}_2 \backslash [\mathbb{P}^1]^n - \Delta],$$

where $\Delta$ is the locus of coincidence of at least two points. Here, $[\mathbb{P}^1]^n$ is acted on by $\text{PGL}_2$ diagonally, and hence, the natural $\mathfrak{S}_n$-action that permutes the factors descends to that on $X(2,n)$. It is known that $X(2,n)$ is an $(n-3)$-dimensional non-singular quasi-projective scheme on $K$. This space comes more visible when one describes it in terms of coordinates: Let $\text{Mat}_{2,n}$ be the affine scheme of all $2 \times n$ matrices. It has the $n$-tuples of column vectors of the form $^t(x_i , y_i)$ $(i = 0, \ldots , n - 1)$ as the coordinate system. Let $D(ij)$ denotes the determinant of the $(i,j)$-minor:

$$D(ij) = x_i y_j - x_j y_i.$$  

Then we have

$$X(2,n) = \text{PGL}_2 \backslash [\text{Mat}_{2,n} - \tilde{\Delta}] / (\mathbb{G}_m)^n,$$

where $\tilde{\Delta}$ is the closed subscheme defined by $\prod_{i < j} D(ij)$, and $(\mathbb{G}_m)^n$ acts on $\text{Mat}_{2,n} - \tilde{\Delta}$ columnwise. The $\mathfrak{S}_n$-action is simply given by the permutation of indices $\{0, 1, \ldots , n - 1\}$.

3.2. The space $X(2,n)$ has the nice projective compactification $\overline{X}(2,n)$, which is the $K$-scheme classifying all stable configurations; see [4, Def. 3.7/Prop. 3.4] for the definition of stable configuration. Denote the open subscheme of $(\mathbb{P}^1)^n$ of stable configurations by $(\mathbb{P}^1)^n_{\text{stable}}$. Then the scheme $\overline{X}(2,n)$ is given by

$$\overline{X}(2,n) = \text{PGL}_2 \backslash [\mathbb{P}^1]^n_{\text{stable}}.$$  

It is well-known that $\overline{X}(2,n)$ is a non-singular projective $K$-scheme of dimension $n - 3$, which contains $X(2,n)$ as a dense open subscheme.

**Examples 3.3.** We will be only concerned with the configuration spaces $X(2,n)$ with $n = 4$ and $n = 5$.

1. If $n = 4$, then $X(2,4)$ is the projective line deprived of three points. Given a rational point of $X(2,4)$, or what amounts to the same, a 4-tuple $(p_0, p_1, p_2, p_3)$ of rational points of $\mathbb{P}^1$ (displayed in terms of inhomogeneous coordinate), one considers the cross ratio $\text{cr}(p_0, p_1, p_2, p_3)$, which gives rise to the open immersion $X(2,4) \hookrightarrow \mathbb{P}^1$. The compactification $\overline{X}(2,4)$ is simply a projective line that fills in the three missing points of $X(2,4)$.  

2. If $n = 5$, then $X(2,5)$ is the projective line deprived of four points. Given a rational point of $X(2,5)$, or what amounts to the same, a 5-tuple $(p_0, p_1, p_2, p_3, p_4)$ of rational points of $\mathbb{P}^1$ (displayed in terms of inhomogeneous coordinate), one considers the cross ratio $\text{cr}(p_0, p_1, p_2, p_3, p_4)$, which gives rise to the open immersion $X(2,5) \hookrightarrow \mathbb{P}^1$. The compactification $\overline{X}(2,5)$ is simply a projective line that fills in the four missing points of $X(2,5)$. 

Another realization is given by the immersion $X(2,4) \hookrightarrow \mathbb{P}^2$ by the map

It maps $X(2,4)$ isomorphically onto the locally closed subset consisting of points $(x : y : z)$ such that none of $x, y, z$ vanishes and that the Plücker relation

$$x - y + z = 0$$

is satisfied.

(2) If $n = 5$, it is known that $\overline{X}(2,5)$ is the Del Pezzo quintic surface. A configuration of 5 points $(p_0, p_1, p_2, p_3, p_4)$ is stable if and only if there exists no subset $I \subset \{0, 1, 2, 3, 4\}$ with $|I| = 3$ such that $p_i = p_j = p_k$. This allows one to describe the boundary $\overline{X}(2,5) - X(2,5)$. In fact, the boundary consists of 10 lines $\ell_{ij}$ defined by the equation $D(ij) = 0$. The line $\ell_{ij}$ is, therefore, the locus of the points representing the configurations of 5 points $(p_0, p_1, p_2, p_3, p_4)$ with $p_i = p_j$; it is thus isomorphic to $\overline{X}(2,4)$, hence to $\mathbb{P}^1$ (3.3 (1)). Each $\ell_{ij}$ intersects exactly 3 other such lines transversally; indeed, the lines $\ell_{ij}$ and $\ell_{kl}$ intersect if and only if $\{i, j\} \cap \{k, l\} = \emptyset$.

The linear system $\tilde{L}$.

3.4. We are going to define a linear system $\tilde{L}$ on the non-singular projective surface $S = \overline{X}(2,5)$. Consider the natural $\mathfrak{S}_5$-action on $\overline{X}(2,5)$ introduced in 3.1. By $\sigma \in \mathfrak{S}_5$, the line $\ell_{ij}$ is mapped linearly to $\ell_{\sigma(i)\sigma(j)}$. Hence, in particular, the divisor

$$\tilde{\Pi} = \sum_{i<j} \ell_{ij}$$

is stable under the $\mathfrak{S}_5$-action.

3.5. Let $\{i, j, k, l, m\} = \{0, 1, 2, 3, 4\}$. Then the line $\ell_{ij}$ intersects $\ell_{kl}, \ell_{lm},$ and $\ell_{mk}$, and these intersection points gives rise to the Hessian duality $\{\tilde{q}^+_{ij}, \tilde{q}^-_{ij}\}$ (2.6). We have 20 such points on $\tilde{\Pi}$ in total. Since the divisor $\tilde{\Pi}$ is stable under the action by $\mathfrak{S}_5$, so is the set of all those points $\tilde{q}^+_{ij}$.

**Definition 3.6.** Define the linear system $\tilde{L}$ on $\overline{X}(2,5)$ by

$$\tilde{L} = \left| \tilde{\Pi} - \sum_{i<j}(\tilde{q}^+_{ij} + \tilde{q}^-_{ij}) \right| = \left\{ \text{effective divisors linearly equivalent to } \tilde{\Pi} \right\}.$$  

As the divisor $\tilde{\Pi}$ and the set $\{\tilde{q}^+_{ij}, \tilde{q}^-_{ij}\}_{i<j}$ are stable under the action by $\mathfrak{S}_5$, the linear system $\tilde{L}$ is acted on by $\mathfrak{S}_5$.

**Pentagonal coordinates.**

3.7. We are going to study the linear system $\tilde{L}$ in more detail. To do this, we are to introduce a useful coordinates on the surface $\overline{X}(2,5)$ following [1].

Given an ordered set $(a, b, c, d, e)$ of indices such that $\{a, b, c, d, e\} = \{0, 1, 2, 3, 4\}$, we put

$$\langle abcde \rangle = D(ab)D(bc)D(cd)D(de)D(4a).$$

Clearly, we have $\langle abcde \rangle = \langle bcdea \rangle$ and $\langle abcde \rangle = -\langle cdbea \rangle$. One $\langle abcde \rangle$ is, therefore, fixed up to sign by the subgroup of $\mathfrak{S}_5$ isomorphic to $\mathfrak{D}_5$, and hence, there exist precisely 12 such symbols.
3.8. There are several relations among $\langle abced \rangle$’s. We first find linear ones as follows: Consider the Kleinian subgroup $\mathfrak{K}_4 = \{1, (ab), (cd), (ab)(cd)\}$ in $\mathfrak{S}_4$ acting on the set $\{a, b, c, d\}$. Then we have

\[ \sum_{\sigma \in \mathfrak{K}_4} \langle abced \rangle^\sigma = \langle abced \rangle + \langle bacde \rangle + \langle abdce \rangle + \langle badece \rangle = 0, \]

which follows from Plücker’s identity $D(ab)D(cd) - D(ac)D(bd) + D(ad)D(bc) = 0$. There are precisely 6 linearly independent such relations.

3.9. For a given $\langle abced \rangle$, its dual is defined to be $\langle acebd \rangle$, that is, the unique one such that any couple of adjacent indices in the former are not adjacent in the latter. We denote it by $\langle abced \rangle^*$. Observe that we have $(\langle abced \rangle^*)^* = -\langle abced \rangle$, hence, despite the name, the formation of taking dual is involutive only up to sign. Note that the product $\langle abced \rangle \langle abced \rangle^*$ is the product of all 10 $D(ij)$’s up to sign, and hence, they are all equal up to sign; checking the sign, we easily see

\[ \langle abced \rangle \langle abced \rangle^* + \langle abced \rangle \langle abced \rangle^* = 0. \]

This gives rise to 5 linearly independent quadratic relations.

3.10. There is yet another series of relations, which is actually given by cubics of $\langle abced \rangle$’s. They are generated, by the $\mathfrak{S}_5$-action, by the one that looks like

\[ \langle abced \rangle \langle abced \rangle \langle abdec \rangle - \langle abdce \rangle \langle abdec \rangle \langle abced \rangle = 0. \]

We have, thus, 10 such cubic relations.

**Definition 3.11.** We set

\[
\begin{align*}
X^* &= (01234), \quad X = \langle 03142 \rangle, \\
Y^* &= (01423), \quad Y = \langle 02134 \rangle, \\
Z^* &= (01342), \quad Z = \langle 04123 \rangle, \\
U^* &= (10234), \quad U = \langle 13042 \rangle, \\
V^* &= (10423), \quad V = \langle 12034 \rangle, \\
W^* &= (10342), \quad W = \langle 14023 \rangle.
\end{align*}
\]

These gives rise to a homogeneous coordinate $(X : Y : Z : U : V : W)$ on $\overline{X}(2, 5)$. In terms of this, the relations (L), (Q), and (C) are now read off as follows:

\[ XX^* = YY^* = ZZ^* = -UU^* = -VV^* = -WW^*, \]

\[
\begin{align*}
X^*Y^*Z^* &= -U^*V^*W^*, \quad XYV^* = -Z^*UW, \\
XYU^* &= Z^*VW, \quad Y^*VW = -XZU^*, \\
Y^*U &= -XZW^*, \quad X^*Y^*W = ZU^*V, \\
YZV^* &= -X^*UW, \quad XV^*W^* = Y^*Z^*U, \\
X^*U &= -YZW^*, \quad X^*Z^*V = YU^*W^*.
\end{align*}
\]
Theorem 3.12. (1) The homogeneous coordinate \((X : Y : Z : U : V : W)\) on \(S = \overline{X}(2,5)\) gives rise to a closed immersion \(\Psi : S = \overline{X}(2,5) \hookrightarrow \mathbb{P}^5\) onto the closed subvariety defined by the relations \((L)\), \((Q)\), and \((C)\), which is nothing but the embedding by the anti-canonical class \(-K_S\).

(2) Consider the homogeneous coordinate \((x' : y' : z')\) given by
\[
\begin{align*}
x' &= D(12)D(03)D(04), \\
y' &= D(13)D(04)D(02), \\
z' &= D(14)D(02)D(03).
\end{align*}
\]
Then it gives rise to the proper birational morphism \(\Psi : S = \overline{X}(2,5) \rightarrow \mathbb{P}^2\) that blows down the 4 lines \(\ell_{0i} (i = 1, 2, 3, 4)\).

Proof. We first show (2). Due to the definition of the stable configuration (as in 3.3 (2)), one sees immediately that the values \(x', y', z'\) cannot be all zero at the same time. Hence it gives the morphism \(\Psi\) as above. To understand it, we may limit ourselves to the locus of \(p = (p_0, p_1, p_2, p_3, p_4)\) with \(z'(p) \neq 0\).

If \(D(01)(p) \neq 0\) and \(D(04)(p) \neq 0\), then one can normalize \(p = (\infty, 0, u, v, 1)\), where \((u, v) \neq (1,1), (0,0)\). Then the map \(\Psi\) on this locus looks like \(\Psi(p) = (u : v : 1)\), hence is one-to-one. In particular, it is a birational morphism. Since \(S\) is proper, \(\Phi\) is a proper mapping.

If in turn \(D(04)(p) = 0\) (the case \(D(01)(p) = 0\) is similar), then \(p\) can be normalized as \(p = (\infty, 0, u, 1, \infty)\), by which we get \(\Psi(p) = (0 : 0 : 1)\). The inverse image of \((0 : 0 : 1)\) on this locus is an affine line. Actually, this gives one affine patch in the blow-up at \((0 : 0 : 1)\); indeed, by the affine coordinate \((x'/z', y'/z')\) on \(\mathbb{P}^2\), one gets \((x'/z') = u(y'/z')\). By this, one easily deduces (2).

For (1), we refer to [1] for the proof that the rational map \(\Phi\) actually gives a closed immersion onto the prescribed closed subvariety. To show that the other statement of (1), one calculates (due to (2)) \(K_S = \Psi^*K_{\mathbb{P}^2} + \sum_{i=1}^4 \ell_{0i}\), whence deducing that \(-K_S\) is the divisor of
\[
\frac{D(12)D(13)D(14)D(02)^2D(03)^2D(04)^2}{D(01)D(02)D(03)D(04)}
\]
(where the numerator stands for \(x'y'/z'\)), that is, in view of Plücker relation (cf. 3.3 (1)), equal to \(ZW/(Z + W)\). Hence we see that \(-K_S = O_S(1)\) as desired.

3.13. Since the surface \(S = \overline{X}(2,5)\) is acted on by the group \(\mathfrak{S}_5\), it is to be checked whether the action is equivalent, through the mapping \(\Phi\), to the Cremona action on \(\mathbb{P}^2\) as in 2.13. Set \(p_1 = (1 : 1 : 1)\), \(p_2 = (1 : 0 : 0)\), \(p_3 = (0 : 1 : 0)\), \(p_4 = (0 : 0 : 1)\). Then the map \(\Psi\) in 3.12 (2) maps the line \(\ell_{0i} (i = 1, 2, 3, 4)\) to the point \(p_i\) and the line \(\ell_{ij} (i, j \neq 0)\) linearly onto the line \(L_{ij}\).

Proposition 3.14. The natural \(\mathfrak{S}_5\)-action on \(S = \overline{X}(2,5)\) is, through the map \(\Psi\), equivalent to the Cremona \(\mathfrak{S}_5\)-action on \(\mathbb{P}^2\); that is, for any \(\sigma \in \mathfrak{S}_5\), we have \(\Psi \circ \sigma = \sigma \circ \Psi\).

Proof. The desired equality \(\Psi \circ \sigma = \sigma \circ \Psi\) are to be checked for the transpositions \((01), (12), (23),\) and \((34)\), which suffices to show the proposition. Let us first check the case \(\sigma = (01)\). In this case, \(\Psi \circ \sigma(p) = (D(02)D(13)D(14) : D(03)D(14)D(12) : D(04)D(12)D(13))\). Dividing out the entries by \(D(12)D(03)D(04)D(02)D(13)\), one gets \(\Phi \circ \sigma(p) = (\frac{y'}{y} : \frac{z'}{z})\), which is nothing but \(J_1(x' : y' : z')\) as in 2.11. In case \(\sigma = (12)\), one calculates \(\Psi \circ \sigma(p) = (-x' : y' - x' : z' - x')\); as the linear transformation \((x' : y' : z') \mapsto (-x' : y' - x' : z' - x')\) is the unique one that exchanges \(p_1\) and \(p_2\) and fixes the other two, we get the desired equality in this case. The other cases are similar.

\(\Box\)
The linear system $\tilde{L}$ as conic section.

**Proposition 3.15.** The divisor $\tilde{\Pi}$ is a conic-cut in $\mathbb{P}^5$ with respect to the embedding $\Phi$; i.e., there exists a quadratic hypersurface $C$ in $\mathbb{P}^5$ such that $\Phi(\tilde{\Pi}) = C \cdot \Phi(S)$. In particular, we have $\tilde{\Pi} \sim \mathcal{O}_S(2)$.

**Proof.** It suffices to invoke the fact that $\tilde{\Pi}$ is the zero set of $XX^* = -X(U + Y + Z)$. \qed

3.16. It is, therefore, natural to ask whether all members of $\tilde{L}$ could be obtained in this way. To check this, we look at the exact sequence

$$0 \rightarrow \mathcal{I}_S(2) \rightarrow \mathcal{O}_{\mathbb{P}^5}(2) \rightarrow \mathcal{O}_S(2) \rightarrow 0,$$

where $\mathcal{I}_S$ is the defining ideal of $\Phi(S)$. The associated cohomology exact sequence begins with

$$(*) \quad 0 \rightarrow H^0(\mathbb{P}^5, \mathcal{I}_S(2)) \rightarrow H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(2)) \rightarrow H^0(S, \mathcal{O}_S(2)).$$

Since $\mathcal{O}_S(2) \cong \mathcal{O}_S(\tilde{\Pi})$, what to prove is the following

**Proposition 3.17.** The map $H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(2)) \rightarrow H^0(S, \mathcal{O}_S(2))$ is surjective. Hence, in particular, every member of $\tilde{L}$ is a conic-cut in $\mathbb{P}^5$.

**Proof.** In the exact sequence $(*)$ in 3.16, the cohomology group in the middle is the space of all quadratic forms, whence having dimension 21, while the first one is the subspace of the quadratic forms whose zero sets contain $\Phi(S)$. Such a quadratic form should belong to $\mathcal{I}_S$, and hence is a linear combination of the known quadratic relations in (Q) in 3.11. As there are exactly 5 linearly independent such quadratic relations, we have $\dim H^0(\mathbb{P}^5, \mathcal{I}_S(2)) = 5$. Therefore, it suffices to show that the dimension of $H^0(S, \mathcal{O}_S(2))$ is 16. Since $\mathcal{O}_S(2) \sim -2K_S$, we deduce by Riemann-Roch Theorem

$$\chi(\mathcal{O}_S(2)) = \frac{1}{2}(-2K_S \cdot (-3K_S)) + \xi(\mathcal{O}_S)$$

$$= \frac{1}{2} \cdot 30 + 1 = 16.$$ 

On the other hand, since $-K_S$ is ample, we have $\dim H^2(S, \mathcal{O}_S(2)) = \dim H^0(S, 3K_S) = 0$. Moreover, by Kodaira-Deligne-Illusie vanishing theorem, we have $\dim H^1(S, \mathcal{O}_S(2)) = \dim H^1(S, 3K_S) = 0$ (for, when $K$ is of positive characteristic, $S$ is liftable to the Witt ring of $K$). Hence $\dim H^0(S, \mathcal{O}_S(2)) = 16$ as desired. \qed

3.18. Consider the subspace $V$ of the quadratic forms in $H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(2))$ defined as follows:

$$V = \left\{ \text{quadratic forms } Q \text{ such that the conic} \right\} \subset H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(2)).$$

Clearly, $V$ contains $H^0(\mathbb{P}^5, \mathcal{I}_S(2))$ as the 5-dimensional subspace. The following theorem completely determines the structure of $V$:

**Theorem 3.19.**

Set

$$F = X^2 + Y^2 + Z^2 + U^2 + V^2 + W^2$$

$$+ X^*2 + Y^*2 + Z^*2 + U^*2 + V^*2 + W^*2,$$

$$G = XX^* + YY^* + ZZ^* - UU^* - VV^* - WW^*.$$ 

Then $F$ and $G$ sit in $V$, spanning an $\mathcal{S}_5$-stable 2-dimensional subspace $V_0$ such that $V = V_0 \oplus H^0(\mathbb{P}^5, \mathcal{I}_S(2))$.

The proof of the theorem will be done in the next section.
Corollary 3.20. (1) The birational morphism $\Psi$ (as in 3.12 (2)) gives rise to the linear isomorphism $\tilde{L} \sim L$ of linear systems, where $L$ is the linear system defined in 2.15 with \( \{p_1, p_2, p_3, p_4\} = \{(0 : 0 : 1), (0 : 1 : 0), (1 : 0 : 0), (1 : 1 : 1)\} \).

(2) The linear system $\tilde{L}$ (and hence $L$ also) is a pencil. Moreover, it is spanned by the two members $\tilde{\Pi} = \{G = 0\}$ and $\tilde{W} = \{F = 0\}$.

(3) General members of $\tilde{L}$ are stable under the action of $\mathfrak{A}_5$, while only $\tilde{\Pi}$ and $\tilde{W}$ are the members that are stable under the action of the whole $\mathfrak{S}_5$.

Proof. In view of 3.17, we see that $\tilde{L}$ is isomorphic to $\mathbb{P}(V_0)$, and hence is a pencil. Moreover, it is spanned by $\tilde{\Pi}$ and $\tilde{W}$. By the birational morphism $\Psi$, the divisor $\tilde{\Pi}$ is obviously mapped to the union $\Pi$ of the 6 lines of the quadrangle spanned by the 4 points $p_i$ (\( i = 1, 2, 3, 4 \)). Moreover, their degree is $2 \cdot 5 - 4 = 6$, and hence, they are sextics. By the definition of $\tilde{L}$, these curves satisfy the conditions (1) (2) in 2.15, and hence belong to $L$. Thus we get a linear map $\tilde{L} \to L$. One can construct (by taking the strict transforms) the inverse mapping $L \to \tilde{L}$. This proves (1) and (2).

To show (3), it suffices to observe that $F$ and $G$ are invariant up to sign under the $\mathfrak{S}_5$-action and that the action on the pencil $\tilde{L}$ is non-trivial (cf. 2.16). But these assertions are clear, for, while $F$ is fixed by any element of $\mathfrak{S}_5$, $G$ is fixed only by even permutations and mapped to $-G$ by transpositions.

Wiman’s sextic: Conclusion.

3.21. As in 3.20 we have two particular members $\tilde{\Pi}$ and $\tilde{W}$ of the linear system $\tilde{L}$, now known to be a pencil. By the linear isomorphism $\tilde{L} \sim L$, $\tilde{\Pi}$ is mapped to the union of 6 lines $\Pi$. It then follows that the image $W$ of $W$ must be the Wiman’s sextic.

It is an easy but tedious job to recover the defining equation of the curve $W$. Let \((x' : y' : z')\) be the homogeneous coordinate of $\mathbb{P}^2$ defined as in 3.12, and then consider the linear change

\[
x = -x' - y' + z', \quad y = x' - y' + z', \quad z = -x' + y' + z'
\]

of coordinates (so that the set $\{p_1, p_2, p_3, p_4\}$ coincides with the set of points $\{(\pm 1 : \pm 1 : \pm 1)\}$.

Then we see that the polynomial $F$ is transformed into the following one:

\[
2[x^5 + y^6 + z^6 + (x^2 + y^2 + z^2)(x^4 + y^4 + z^4) - 12x^2y^2z^2].
\]

3.22. One sees easily, by means of the coordinates $X, Y, \ldots, W$, that the 6-dimensional representation $H^0(\mathbb{P}^5, O_{\mathbb{P}^5}(1))$ of $\mathfrak{S}_5$ is the unique irreducible one. The induced action on the space of quadratic forms $H^0(\mathbb{P}^5, O_{\mathbb{P}^5}(2))$ is isomorphic to the second symmetric product of the first one, and hence the irreducible decomposition can be easily calculated:

\[
H^0(\mathbb{P}^5, O_{\mathbb{P}^5}(2)) = (\text{triv}) \oplus (\text{sgn}) \oplus (4^+) \oplus (5^+)^2 \oplus (5^-).
\]
where ((triv) (resp. (sgn)) is the trivial (resp. signature) representation, and $(n^+)$ denotes the $n$-dimensional irreducible representation such that the signature of the trace of transpositions is ±. By a slightly more calculation one sees that the component $(5^-)$ is the subspace $H^0(\mathbb{P}^5, \mathcal{I}_5(2))$ (having the basis $XX^* - YY^*$, $YY^* - ZZ^*$, $ZZ^* + UU^*$, $UU^* - VV^*$, $VV^* - WW^*$). The subspace $V_6$ is the direct sum of the first two components; $F$ is a basis of the trivial part, and $G$ of the signature part.

4. Proof of Theorem 3.19

In this section, we prove Theorem 3.19. The proof is divided into several steps.

4.1. First we write the equation in $\mathbb{P}^5$ of lines, which can be easily done by the fact $\ell_{ij} = \{D(ij) = 0\}$. For the later use, we divide these equations into 3 types:

\[
\begin{cases}
\ell_{04} : Y = Z = U = W = 0, \\
\ell_{13} : X = Y = U = W = 0, \\
\ell_{02} : X = Y = V = W = 0, \\
\ell_{14} : X = Z = V = W = 0, \\
\ell_{03} : X = Z = U = V = 0, \\
\ell_{12} : Y = Z = U = V = 0.
\end{cases}
\]

(1)

\[
\begin{cases}
\ell_{24} : X = U = Y + W = Z + V = 0, \\
\ell_{34} : Y = V = X + W = Z + U = 0, \\
\ell_{23} : Z = W = X + V = Y + U = 0.
\end{cases}
\]

(2)

\[
\ell_{01} : X - U = Y - V = Z - W = X + Y + Z = 0.
\]

Let $Q$ be a quadratic polynomial in $H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(2))$. For a monomial, say $XY$, we denote the coefficient of $XY$ in $Q$ by $q_{XY}$, etc.

4.2. We look at the condition that $Q = 0$ passes through the points $q_{04}$. By the first row in (1) in 4.1 the line $\ell_{04}$ has the homogeneous coordinate $(X : V)$. This line has the intersection points with $\ell_{12}$, $\ell_{23}$, and $\ell_{13}$, which are easily calculated to be $(1 : 0)$, $(-1 : 1)$, and $(0 : 1)$, respectively. By this one calculates the Hessian dual $\tilde{q}_{04}^\pm$ to be $\{(\omega : 1), (\omega^2 : 1)\}$, that is, the zeros of $X^2 + XV + V^2$. Hence the condition in question is

\[ q_{X^2} = q_{XY} = q_{Y^2}. \]

We do the same for all the line listed in (1) in 4.1. Consequently, we get 12 equalities among the coefficients that stand cyclically

\[ q_{X^2} = q_{XY} = q_{Y^2} = \cdots = q_{W^2} = q_{WX} = q_{X^2} \]

with respect to the ordering

\[ X \sim V \sim Z \sim U \sim Y \sim W \sim X. \]

We get, therefore, precisely 11 linearly independent relations among coefficients.

4.3. Next, we consider the points $q_{ij}$ on the 3 lines in (2) in 4.1. The line $\ell_{23}$, for example, has the homogeneous coordinate $(X : Y)$, and, in terms of it, the intersections with $\ell_{01}$, $\ell_{14}$, and $\ell_{40}$ are $(-1 : 1)$, $(0 : 1)$, and $(1 : 0)$, respectively. Hence the situation is parallel to the previous one. The condition is

\[ Q(X, Y, 0, -Y, -X, 0) = \lambda(X^2 + XY + Y^2) \]

ON THE GEOMETRY OF WIMAN’S SEXTIC

11
for some $\lambda \in K$. Since the coefficients of $X^2$ and $Y^2$ in the left-hand side are, as we say in the previous step, equal to each other, we have precisely one relation that gives $q_{XY}$. Similar observation on $\tilde{q}_{24}^\pm$ and $\tilde{q}_{34}^\pm$ gives relations involving $q_{YZ}$ and $q_{ZX}$, and hence, we have so far $11 + 3 = 14$ linearly independent conditions on the coefficients.

4.4. Finally, we look at $\ell_{01}$ characterized by (3) in 4.1. By an argument similar to that in the previous steps, we deduce that the condition is

$$Q(X, Y, -X - Y, X, Y, -X - Y) = \lambda (X^2 + XY + Y^2)$$

for some $\lambda \in K$. Now the coefficients of $X^2$ in the left-hand side is

$$q_{X^2} + q_{Z^2} - q_{XZ} + q_{W^2} + q_{XW} - q_{XY} - q_{ZW} + q_{ZW} = 2q_{X^2};$$

similarly, the coefficient of $Y^2$ is equal to $2q_{X^2}$, while that of $XY$ is

$$q_{XY} - q_{XZ} + q_{XW} - q_{YW} + q_{XY} + 2q_{Z^2} - q_{ZU} - q_{ZV} + 2q_{ZW} + q_{VU} - q_{YW} - 2q_{W^2} = 2q_{X^2}.$$ 

Hence the condition in question is already satisfied, and is superfluous. We conclude, therefore, that the condition of passing through the 20 points $\tilde{q}_{01}^\pm$ is exactly of rank 14, and hence that $\dim V = 21 - 14 = 7$.

4.5. Since $\tilde{\Pi} = \{G = 0\}$, we have $G \in V$. Moreover, it is clear that $G \notin H^0(\mathbb{P}^5, \mathcal{I}_S(2))$, since it cuts out the divisor $\tilde{\Pi}$ on $S$. To prove that $F \in V$, it is enough to show that $F = 0$ contains $\tilde{q}_{01}^\pm$, for $F$ is clearly $\mathfrak{S}_5$-invariant. This follows from

$$F|_{D(01)=0} = F(X, Y, -X - Y, X, Y, -X - Y) = 4(X^2 + XY + Y^2)$$

due to (3) in 4.1. Since $G$ is not invariant under the $\mathfrak{S}_5$-action, $F$ is not proportional to $G$. Since the quadratics $XX^*, YY^*, \ldots, WW^*$ do not contain the monomials $X^2, Y^2, \ldots, W^2$, $G$ does not either, while one sees easily that $F$ contains them. Since

$$XX^* - YY^*, YY^* - ZZ^*, ZZ^* + UU^*, UU^* - VV^*, VV^* - WW^*$$

give a basis of $H^0(\mathbb{P}^5, \mathcal{I}_S(2))$, every element in $H^0(\mathbb{P}^5, \mathcal{I}_S(2))$ does not contain the monomials $X^2, Y^2, \ldots, W^2$. Hence $F \notin H^0(\mathbb{P}^5, \mathcal{I}_S(2))$. Since $G \notin H^0(\mathbb{P}^5, \mathcal{I}_S(2))$, any linear combination of $F$ and $G$ but 0 does not belong to $H^0(\mathbb{P}^5, \mathcal{I}_S(2))$, and hence, we have $V_0 \cap H^0(\mathbb{P}^5, \mathcal{I}_S(2)) = \{0\}$. Counting the dimension, we get $V = V_0 \oplus H^0(\mathbb{P}^5, \mathcal{I}_S(2))$, as desired.
